ABSTRACT

Depression and type II diabetes mellitus (T2DM) are costly and chronic conditions. This study investigated depression treatment, i.e., antidepressant pharmacotherapy (AP) or pharmacotherapy plus psychotherapy (AP+P), and associated healthcare costs and utilization in a real-world setting for patients with comorbid T2DM. We hypothesized that patients who initiate depression treatment should have a reduction in healthcare costs compared to a 12-month pre-period with no depression treatment. Further, the specific costs for emergency department (ED) visits should decrease with depression treatment. We also hypothesized that patients in the AP and AP+P groups would show a cost-benefit once receiving treatment for depression. This was a retrospective study using claims data from the ThomsonReuters MarketScan® Research Database for privately insured patients during the calendar year 2002-2003. The study cohorts, $n = 927$ per group, were created using propensity score matching and analyzed with multivariate statistical methodologies. We calculated benefit-cost ratios (BCR) for healthcare costs during the 12-month post-period. The mean number of outpatient visits for T2DM-related healthcare increased for the AP+P from 10.1 per patient in the pre-period to 16.1 in the post-period. Medication adherence was higher for the AP group with odds ratio for nonadherence 1.88, 99% CIs [1.26, 2.69] for the AP+P group. Total depression-related treatment cost for the AP group,

was \$1,101 ($SD = \885) and for the AP+P group it was \$905 ($SD = \$3,108$) per patient. We found a statistically significant decrease in T2DM-related inpatient costs for the AP+P group with \$675 ($SD = \807) per patient in the post-period. However, the outpatient costs increased by \$688 ($SD = \510). The results of the BCR indicated that the total amount of dollars invested for depression treatment was greater than the total cost difference, i.e. savings, for all other healthcare services and for services for T2DM for both the AP and the AP+P group. Following treatment selection of AP or AP+P, patients with depression and T2DM had very few statistically significant differences. However, patient selection of AP+P may enhance health-related benefits by increasing T2DM outpatient visits that incorporate preventative care and consequently resulted in the reduction of amputation and renal disease compared to the AP group. Conversely, the AP group had a significantly higher rate of medication adherence compared with the AP+P group. Higher medication adherence may have resulted in the AP group's reduction of hypertensive disease, a medical comorbidity typically treated with medication. Limitations in our study included the general issues with claims data research including interpretation of coding, and generalizability of our sample to the population. Despite the limitations, this study provided a broad view of the year following initiation into depression treatment. The results indicated that treatment for depression influences not just depression, but comorbid chronic conditions such as T2DM. The present study highlights the continued need for research in the integration of healthcare services in order to reduce costs, improve health and potentially augment quality of life.

CHAPTER 1

INTRODUCTION AND BACKGROUND

The combination of clinical depression and type II diabetes mellitus (T2DM) is a potentially harmful comorbidity as it impacts the course of treatment for both conditions. Research has demonstrated a consistent association between the combination of T2DM and depression and increased healthcare service costs (Simon et al., 2007). Because the increase in healthcare costs and service use are attributed to comorbidity, in this study we investigated the impact that depression treatment initiation has on overall healthcare costs and T2DM costs. We hypothesized that effective depression treatment could yield an overall healthcare cost savings.

Impact of T2DM with Comorbid Depression

Prevalence. Depression and T2DM are common chronic conditions in the United States population. In the survey year closest to when our research data were collected, 2005, an estimated 9.5% of adults in the United States were diagnosed with depression (National Institute of Mental Health, NIMH, 2007). For T2DM, in 2005, the prevalence was estimated at about 23.5 million adults, or 10.7% of the US population (Centers for Disease Control, CDC, 2007). The co-occurrence of depression and T2DM is high. About 20 to 25 percent of patients with T2DM have comorbid depression (Yavar & Mashinchi, 2010). Overall, patients with T2DM are twice as likely to have depression as patients without T2DM (Roy & Lloyd, 2012; Schneider & O'Donnell, 2009).

Cost. Depression and T2DM are also costly conditions. NIMH estimated that the total annual cost for depression in the United States was about \$83 billion in 2002 (NIMH, 2002). From this total cost, only \$26 billion was spent directly on medical treatment. More than double the treatment cost, \$57 billion, was due to illness-related issues such as absenteeism, loss

in work-related productivity, and loss in lifetime earnings due to suicide. In 2005, the closest year to 2002 for which data were available, the estimated direct and indirect costs for T2DM totaled \$174 billion (CDC, 2007). Roughly \$116 billion of the total cost for T2DM was the direct costs of medical care. The remaining indirect costs, \$58 billion, included disability, loss in productivity, and premature death.

Cost and comorbidity. Comorbidity of depression and T2DM results in more total healthcare spending than either condition alone. Patients with comorbid T2DM and depression have direct healthcare related costs an average of 4.5 times more than patients with only depression or T2DM (Eged, 2004). The increase in cost, however, is not due to the sum of depression treatment and T2DM treatment. Unutzer and colleagues (2003) found that depressed patients with another chronic condition spent only 1 percent of total healthcare dollars on mental health treatment. Increased costs are overwhelmingly due to greater use of physical medical services rather than use of depression treatment (Henk et al., 1996; Simon, VonKorff, & Barlow 1995). Cost differences between patients with and without depression persist even when accounting for comorbid chronic medical illness.

Healthcare utilization. Cost is directly related to healthcare service utilization. Utilization patterns are different for patients who have comorbid depression and T2DM rather than either condition alone. The differences are seen across settings, including emergency department (ED) visits, outpatient visits, and hospitalizations. ED visits are often preventable for patients with depression and another chronic condition (Gulley & Rasch, 2010). Patients with depression have increased ED visits for mental health reasons and also for complications related to a chronic medical condition such as T2DM (Yu et al., 2011).

In addition to increased ED utilization, there may be a relationship between depression and use of outpatient health services. Koenig and Kuchibhatla (1998) found that depressed elderly patients used more outpatient services than nondepressed elderly patients. However, the difference in outpatient use was not due to mental health treatment. In a recent study, patients with T2DM and depression used more outpatient general medical care than patients with T2DM without depression (Le et al., 2011). Research has indicated that the presence of depression seems to increase all outpatient service utilization (Crown et al., 2002; Egede et al., 2002). Even when excluding mental health visits, patients with depression and T2DM sought care at outpatient clinics and providers more than nondepressed patients.

Finally, patients with both depression and T2DM have lower medication adherence than patients with just one of the chronic conditions alone. In 2009, Kurlander and colleagues found that patients with T2DM and any depressive disorder were about 16% more likely to skip doses in a T2DM medication regime than patients with T2DM alone. The investigators found the same proportion of noncompliance with medication regimes even when controlling for cost-related issues such as insurance status and out-of-pocket payments for medication. Medication adherence is a significant factor for the prognosis of depression and a concurrent medical disorder.

Without proper treatment, depression can negatively impact overall health. Increase in total healthcare costs, over-utilization of the ED, and longer hospital stays are some of the major outcomes for patients without adequate treatment (Kessler et al., 2008).

Depression treatment selection. The consistent association between depression and increased health care costs suggests that an investment in depression treatment could be offset by decreases in other general medical care costs. Although studies have shown that antidepressant

pharmacotherapy alone can be effective for reducing depression, the effectiveness of medication for depression can be augmented by psychotherapy (Antonuccio, 1995; Frank 2000; Segal, Vincent, & Levitt, 2002; Simon et al., 2007).

In a randomized controlled trial (RCT), Simon and colleagues (2007) found that adding cognitive-behavior therapy (CBT) to an antidepressant pharmacotherapy regime for T2DM patients with depression increased depression-free days and reduced outpatient costs over a 24-month period. The total net benefit was about \$950 per patient for the 24 months when patients were treated with psychotherapy and pharmacotherapy, even including the cost of the additional psychotherapy treatment. A randomized clinical trial in 2002 found that combined treatment, i.e., psychotherapy (brief CBT) and clomipramine, resulted in an average cost savings of \$2,311 per patient over a 12-month period (Burnan et al., 2002). The researchers concluded that cost savings was driven primarily by a reduction in hospital stays and fewer work days missed. Previous research demonstrated that psychotherapy in conjunction with antidepressant pharmacotherapy may decrease all healthcare costs, especially more costly ED visits. In a randomized controlled trial, Antonuccio et al. (2000) found that psychotherapy (CBT) plus Prozac resulted in a cost savings of approximately \$596 per patient over a 2-year period. The cost savings was found due to a decrease in ED use. The investigators concluded that psychotherapy aided in drug adherence and prevented relapse.

Current Study

RCTs, like the studies above, can provide information on treatment efficacy. However, such studies seldom provide external validity or address the effect depression treatment has on health service utilization and healthcare costs outside of a controlled setting. Observational

studies, although not as rigidly controlled, are valuable in providing an overall picture of healthcare resource use and highlight areas for cost savings.

The purpose of our research was to examine how healthcare costs and utilization patterns change when a patient with T2DM initiated depression treatment. We used data from commercial, employer-sponsored, insurance claims in a real-world setting. We investigated patients with T2DM during a 12-month pre-period with no depression treatment and compared it with healthcare costs and utilization up to 12 months after patients started treatment for depression. Additionally, we examined if there was a difference in costs and healthcare utilization associated with two different depression treatments, antidepressant pharmacotherapy (AP) or pharmacotherapy plus psychotherapy (AP+P). We defined the monetary benefits as the difference in pre and post-period healthcare costs, and costs as the investment in depression treatment. Due to the limitations of using claims data, we were not able to account for any additional benefits like work productivity, increase in employee income, or quality of life factors. We were, however, able to include all healthcare costs, across multiple provider settings, in our analyses.

We evaluated any potential cost-benefit for selecting one of the two treatments using a benefit-cost ratio (BCR). Our analysis included the difference in all healthcare costs and specific T2DM-related costs before depression treatment and after depression treatment per patient, divided by the costs for the select depression treatment per patient. Based on similar previous research with RCTs, we hypothesized that there would be an overall decrease in healthcare costs and, more specifically, a decrease in ED costs. The decrease in ED costs would offset the cost of depression treatment so that, per patient, the BCR would yield a total savings. Additionally, we

predicted that the AP group would be associated with a significantly smaller BCR per patient, compared with the AP+P group.

Existing research that uses similar claims survey methods has focused on the descriptive nature of having both T2DM and depression (Kalsekar et al., 2006; Katon, et al., 2008; Shen et al., 2010). Additional studies have investigated factors such as a) prevalence in sub-populations (Seftel, Sun, & Swindle, 2004), b) costs and healthcare utilization for patients with both disorders (Boulanger et al., 2009), or c) indirect cost of illness studies focusing on employment loss of productivity (Conti & Burton, 2005). These studies examined the effect depression has on outcomes similar to those we are investigating in this study. Past studies, however, have not researched the impact that treatment selection, AP or AP+P, has on all healthcare costs.

Additionally, there are few longitudinal studies that have investigated depression treatment selection and the associated treatment patterns for chronic medical conditions. A large percentage of patients with a chronic health condition have comorbid depression (Egede & Ellis, 2010). Comparisons between outcomes, costs, health service utilization, and treatment effectiveness had been done with RCTs with little emphasis on real-world treatment patterns. The current study was one of the only large retrospective claims studies to investigate the impact of depression treatment on costs and utilization among individuals with comorbid depression and T2DM.

CHAPTER 2

METHOD

Research Design

This was a retrospective study that analyzed data from employer-sponsored health insurance claims. Data were from the MarketScan Commercial Claims and Encounter Database (ThomsonReuters, New York, NY 2002). The population was insured persons and their dependents who received private insurance through a number of large employers throughout the United States for the period from January 2002 to December 2003. We investigated costs and utilization for total depression-related and T2DM-related healthcare across all settings including inpatient, outpatient, emergency department, and prescription drugs.

The health plans were employer-sponsored private plans, which included fee-for-service and capitated health insurance. This database was a nationwide convenience sample of patients. The specific plan names and employers were not released with the data. The database complies with the Health Insurance Portability and Accountability Act (HIPAA). Patients were assigned unique numbers to ensure that individual patients could not be identified. This study was conducted after the approval of the American University Institutional Review Board and with permission from ThomsonReuters.

Study Cohorts

Patients were followed only if they had 24 months of continuous enrollment in a health plan. The pre-depression treatment period referred to as the *pre-period* included data from January 1, 2002 through December 31, 2002. The index date was defined by the date the patient had a claim for either an antidepressant or psychotherapy after December 31, 2002. The period after a patient selected treatment for depression was referred to as the *post-period*. The post-

period was therefore based on a moving index date, defined by when the patient initiated pharmacotherapy or psychotherapy for depression. The post-period included data from January 1, 2003 to December 31, 2003.

Our sample included adult patients (18-64 years of age) with a diagnosis of T2DM in the 12-month pre-period. A T2DM diagnosis was defined by the presence of at least one claim in 2002 with an International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) code 250.x0 or 250.x2 only. Patients were excluded if they had any claims during the pre-period for gestational diabetes (ICD-9-CM code 648.8×) or type I diabetes (ICD-9-CM codes 250.x1 or 250.x3, or Diagnosis-Related Group code 295).

From the T2DM sample we then extracted data for patients who had submitted at least 2 claims with a diagnosis of depression at least 30 days apart during January 1, 2002-December 31, 2003 (Table 1). Based on methods that used claims data in previous research investigating patients with depression (Gibson et al., 2010), patients were excluded from the study for select ICD-9-CM diagnoses (Table 1).

Table 1. ICD-9-CM Inclusion and Exclusion Criteria

Included		Excluded	
ICD-9-CM Code	Description	ICD-9-CM Code	Description
296.2x	Major depressive disorder, single episode	648.4x	Postpartum depression
296.3x	Major depressive disorder, recurrent episode	290.xx	Dementia
300.4	Dysthymic disorder, depression with anxiety; depressed reaction	295.xx	Schizophrenia
309.0	Adjustment disorder, with depressed mood	297.xx	Delusional disorder
311.xx	Depressive disorder, NOS, not elsewhere classified	298.xx	Other nonorganic psychoses
		299.xx	Pervasive development disorder
		317.xx-319.xx	Mental retardation
		331.xx	Other cerebral degenerations
		332.xx	Parkinson's disease
			Senility without mention of psychosis
		787.xx	
		296.0, 296.1, 296.4, 296.5, 296.7, 296.80, 296.81, 296.89	Codes for manic depression or bipolar disorder

Once we established the depression and T2DM cohort, we then excluded patients with any claim for an antidepressant as defined by National Drug Codes (NDC) (Appendix A) during the 12-month pre-period. We then examined the 12-month post-period and selected patients who had at least one claim for any of the select antidepressant medications. Outpatient psychotherapy was categorized by Current Procedural Terminology (CPT) codes and included codes that comprised individual outpatient psychotherapy (Appendix B). We excluded claim codes that would indicate the psychotherapy was specifically only for smoking cessation or alcohol or drug treatment, psychodiagnostic evaluation, or indicated less than 15 minutes with a provider. From this sample, we created the two study group cohorts for analysis.

In summary, both the AP and the AP+P group consisted of patients with T2DM in the pre-period and at least two claims for depression in either the pre or the post-periods. Patients in both groups had at least one claim for antidepressant medication during the 12-month post-period. In addition to an antidepressant medication claim during the 12-month post-period, patients in the AP+P had at least one psychotherapy claim in the 12-month post-period.

Propensity Score Matching (PSM)

Propensity score matching (PSM) was used to balance the two different intervention groups on observed covariates to obtain accurate estimates of the effects of treatment rather than the influence of confounding differences in the population. PSM mitigated the possibility that differences found between the two groups of patients in the post-period were attributed to pre-period differences on demographic or other variables. However, to the extent that there are unobservable differences that were not highly correlated or not available within the observed characteristics or data set, selection bias may still exist even after matching. For example, how long patients had undiagnosed depression, but not sought treatment, could have influenced treatment selection and outcomes.

The present study was based on insurance claims in a large (millions of records) database. As the data were from a real-world setting, patients selected their treatment based on characteristics that potentially varied among treatment groups, leading to possible selection bias. PSM techniques were useful in our study because such techniques controlled this selection bias (for justification see Rosenbaum & Rubin, 1983). In the present study, PSM was used to match patients in the AP group to patients in the AP+P study group according to a set of similar characteristics to better elucidate the difference in costs, healthcare utilization, and medication adherence associated with selection of one or the other study groups.

This study used the *caliper method* of PSM (D'Agostino, 1998). The caliper method matched based on the explanatory variables score within a set range (i.e., caliper). For this study, we first found the absolute difference of the propensity score between a patient in the AP and the AP+P group and then calculated if that difference was within a specific range (see Appendix C). The specific range, or *tolerance range*, for this study were within one-quarter the standard error of the propensity scores (For justification see Austin, 2009 Austin, 2011a; Austin, 2011b). Patients in the AP+P study group were matched to patients in the AP study group. A bad match meant the score of the AP patient was either high or low. The difference in scores meant the characteristics of the AP patient would not be similar to the AP+P subject and could create a potential confound. If the match was not within this set range, the patient in the AP group was discarded and another match was attempted. The caliper method required fewer comparisons when good matches were not available, as fewer patients would meet the stricter requirements for a match. Selecting a range of acceptable scores, i.e., within the 0.25 caliper range, also reduced the possibility of selection bias (Dehejai & Wahba, 2002).

Explanatory variables. For this study we incorporated a number of explanatory variables in generating our final study population. The explanatory variables included demographics variables, medical variables, healthcare utilization patterns, and pre-period costs. Research often has focused on factors that keep patients from initiating depression treatment, including physician training (van Belljouw et al., 2010), patient race (Bao et al., 2011; Shellman & Mokel, 2010), or cost (Goldberg & Steury, 2001). However, a few studies (Dwight-Johnson, Sherbourne, & Wells, 2001; Fortney, Rost, & Zhang, 1998) have focused on patient factors that are associated with selection of AP or AP+P, including age, sex, comorbid condition, or insurance plan type that may dispose a patient to select AP or AP+P in a real-world setting.

Therefore, in this study we included the following patient demographics that may have influenced which treatment group the patient selected: a) index date or the date when AP or AP+P group assignment has been established, b) gender, c) geographic region as coded in the database as West, North East, South, and North Central d) age, e) age-squared, as middle-aged adults are at a lower end of costs with a nonlinearity distribution of costs attributed to increasing age older. By using age squared we captured the nonlinearity in the relationship. We also incorporated health insurance plan type including preferred provider organization, health maintenance organization, or point-of-service plans. Plan type could have influenced how patients selected their treatment due to the impact on out-of-pocket costs or what services are covered under the plan (Frank et al., 1996).

Additionally, severity and complexity of an individual patient's prognosis may change overall healthcare utilization and the cost of the illness. Therefore, we included medical variables to describe severity in the matching process. Patients with depression and a previous psychiatric hospitalization may be more likely to receive the AP+P treatment than depressed patients who have never been hospitalized (Huff, 2000). However, these patients are also more likely to be re-hospitalized, have more healthcare utilization overall, and be more costly. Therefore, prior psychiatric hospitalization in the pre-period was included as a medical characteristic that may influence post-period treatment selection.

Research has also indicated that total healthcare costs are a potential indicator of disease severity (Ciechanowski et al., 2000; Druss et al., 1999). The total cost of healthcare in the pre-period was therefore included in the model created for the PSM. We used the total healthcare expenditures in the pre-period across settings for patients. Expenditures were measured as a

categorical variable for the quartiles of spending based on the distribution of costs around the pre-period mean of all health care spending per patient.

We also investigated the probability that an individual selected AP or AP+P with medical characteristics related to disease severity. These characteristics may have confounded our outcomes of interest. We assessed for comorbidity (for justification see Quan, Parson, & Ghali, 2002; Schneeweiss et al., 2001). Comorbidity was measured using the both the Charlson-Deyo Comorbidity Index (CCI) for matched case-mix and severity (see Appendix D) and the total Chronic Disease Score (CDS). The CCI is the most commonly used index score for MarketScan data studies (Deyo, Cherkin, & Ciol, 1992). We also matched on the presence of any other mental health or substance abuse disorder, for example anxiety disorders or alcohol abuse diagnosis based on the presence of an ICD-9-CM code on any of the claims during the pre-period. We included psychiatric hospitalization (for codes see Appendix E), ED visits related to psychiatric condition (for codes see Appendix E), and hospitalizations self-harm/suicide behaviors (for codes see Appendix E) during the pre-period.

The demographic and medical variables were included to correct for some counterfactuals between the study groups. Once we matched and analyzed the pre-period data and ensured that no statistically significant differences were found, we then looked at the dependent variables in the post-period to investigate the impact of AP or AP+P group.

Dependent (outcome) variables. The purpose of the current study was to make inferences about the relationship between the cost-benefit of the two treatment patterns in the study groups. To do this, we analyzed the real-world healthcare cost and utilization pattern for patients with T2DM and depression. To get a broad picture of healthcare, the outcome variables need to describe not only the cost and healthcare utilization related to T2DM and depression, but

also the total healthcare utilization and costs. Generalized Linear Modeling (GLM) assessed the relationship of study group assignment and cost for the total healthcare, T2DM-related costs, and depression-related costs. In the GLM we assumed that the variance around the mean was either a linear or exponential function of the explanatory variables (the PSM).

The outcomes variables included counts for healthcare utilization divided into a) depression healthcare service utilization, b) T2DM healthcare service utilization, and c) all other healthcare service utilization. Service utilization included: inpatient, outpatient, ED, and pharmacy. Additional treatment outcomes included medication adherence.

As insurance claims datasets, such as MarketScan, are originally created for payment, they do not include any clinical data to assess patient ratings of treatment effectiveness. Therefore, we could not investigate patient assessments to measure a reduction in distress, such as Beck Depression Inventory scores. The treatment outcomes were predicted to be better for the AP+P group versus the AP group as shown by the research reviewed for this study. However, we expected that the AP and AP+P would decrease all ED visits. Cost included only the total monetary cost of health services, insurance paid, and out-of-pocket expenses, including copayments and coinsurance.

Final study cohorts. A total of 24,841 patients met the initial selection criteria for patients with T2DM with comorbid depression. Roughly 91 percent of these patients were engaged in depression treatment during the pre-period and therefore did not meet the inclusion criteria in our study. After matching, based on the AP+P cohort, approximately 1.7% of patients ($n = 16$) were dropped due to an inability to find an appropriate match or due to data inaccuracies, including negative numbers, such as negative dates during the pre-period. The final number of patients included in our study was 927 patients per study group.

Data Analysis

Statistical tests. All analyses were conducted using SAS version 9.1 (SAS Institute, Inc., Cary, North Carolina, 2006). Due to the large sample size in this study, we used alpha level $p < .01$ for all statistical tests. Data for healthcare services and costs are usually right-skewed and truncated at zero due to a small number of patients with high costs, a large number of patients with no costs, and the impossibility of costs less than zero. Based on the non-normal distribution of healthcare costs, Wilcoxon rank sum tests were used for comparison of continuous variables. The Maentel-Haenszel χ^2 test (Fleiss, Levin, & Paik, 2003; Wittes & Wallenstein, 1998) was used for comparison of categorical variables. Numbers and percent were provided for dichotomous and polychotomous variables, such as gender, plan type, and region. Means, standard deviations, and percentiles were provided in the results tables for continuous variables, such as costs. To compare the mean differences in costs between the pre-period and the post-period we used the Wilcoxon-signed rank test due to the non-normal distribution of that data. Odds ratios (OR) were calculated for medical variables including comorbid conditions and medication adherence. OR are useful when determining the likelihood that a given condition, e.g., a specific comorbidity, will occur given a particular exposure or study condition. For the purpose of our study, OR were used to determine the presence or absence of a disease in the post-period given the number of expected cases from the pre-period.

We tested for heteroscedasticity using the White test (White, 1980). Tests for heteroscedasticity are useful because they can show if the regression model has a variance of the errors that is constant across observations. If the errors have constant variance and the White test is not statistically significant, the errors are called homoscedastic. The White test is often used in economic research and is especially useful for healthcare research because of the large variance

around the mean for costs and utilization at the individual patient level (Kim, Morse, & Zingales, 2006). A similar statistical technique was used in research on claims data set to test for variance around the mean (Blough & Ramsey, 2000). The impact of cost and study group assignment was assessed during the post-period within this model and outliers were discarded due to a small sample ($n < 5$) with negative costs and costs stated to be over three million for the year.

Benefit-cost ratio (BCR). BCR analyses calculated the investment (monetary input) for AP or AP+P during the post-period and the total change in pre-period and post-period healthcare costs of all other services. The net benefit per patient was calculated based on costs of all other (non-depression) related health spending in the post-period compared with the pre-period costs. We specifically looked at T2DM-related costs and ED costs. As the AP and the AP+P groups were created based on specific depression-related treatment, either pharmacotherapy or pharmacotherapy and psychotherapy, we did not include costs for depression related to inpatient and ED visits in our BCR. However, as depression hospitalizations and ED visits were characteristics matched during the pre-period, we were able to account for the differences between the two groups for these services with the PSM.

To create the BCR, we first examined cost of treatment for depression for AP or AP+P. This was the cost, or the denominator in our ratio. We used a Wilcoxon-signed rank test to determine any statistically significant difference in the mean cost for treatment from the pre-period to the post-period. We then compared the savings (benefits) for other health-related cost and T2DM-related costs per patient. In this study the benefits would be the potential reduction in costs from the pre-period to the post- period in all nondepression healthcare spending and T2DM-related expenditures. The difference in pre-period and post-period was used as the benefit or the numerator in our ratio. The benefit-cost ratio (BCR) was considered to show a benefit if

the ratio per patient was greater than 1. We also conducted a nonparametric bootstrapping analysis as an alternative approach to the Wilcoxon-ranked sign. Results and description of this analysis can be found in Appendix F.

For all cost analyses, cost was adjusted using the annual Medical Care Component of the Consumer Price Index (CPI) to reflect 2003 dollar amounts. In this study, the CPI was 3 percent more in 2002 for every dollar spent in 2003, meaning each value in our dataset in 2002 was multiplied by 1.03. This was done in order to account for price inflation across the two years of study (Bureau of Labor Statistics, 2011). The Medical Care Component was used to adjust for inflation instead of the general inflation index. We used this rate because it specifically reflects the high inflation costs related to medical care versus other service industries.

Adherence measures. Adherence to antidepressant medication was analyzed using the proportion of days covered (PDC) by the antidepressant medication prescription. The PDC was calculated using the number of days when medication was prescribed divided by the number of days in the period. This estimate indicated the amount of time a patient had a gap in prescription. For example if a patient had a 30-day prescription and the claim showed 45 days between refills then 15 days were considered *uncovered*. The PDC has been used as an estimate for adherence in several prior studies that use large claims data (Farley et al., 2012; Karve et al., 2009). If a patient has less than 80 percent of PDC they were categorized as nonadherent to antidepressant medication (Hess, Raebel, Conner, & Malone, 2010).

CHAPTER 3

RESULTS

Patient Variables

Table 2 shows the final cohort demographics. After matching there were no statistically significant differences in the demographic variables of interest. After matching, 46% ($n = 426$) of the patients were male, 54% ($n = 501$) were female. The mean age in the AP group was 47.2 years and 45.7 years for the AP+P group. There was no statistically significant difference in the mean age, $p = 0.41$. The majority of the patients were in the age group 45-54 years, approximately 42%. There was no statistically significant difference between the distribution of the age groups for the AP and AP+P group after PSM. Patients in both groups had more than 50% enrollment in capitated health care plans. Around 60% of the patients were the primary enrollees rather than spouses or other dependents in this study.

Table 1 also shows the region where the patients filled their health claims. Roughly 30% of patients were located in the South and 30% in the Northeastern regions of the US. The West made up about 23% for the AP group and 24% of patients in the AP+P group. The remainder, 16% for the AP and 15% for the AP+P group, were located in the North Central region. As MarketScan is a convenience sample, it cannot be assumed that the geographic region distribution is generalizable to the U.S. population.

Table 2. Patient Variables for Pharmacotherapy and Pharmacotherapy plus Psychotherapy after Propensity Score Matching, 2002

Patient Variable	Pharmacotherapy		Pharmacotherapy plus Psychotherapy		p-value

Medical Variables

After PSM there were no statistically significant differences in the medical characteristics for the AP and the AP+P group during the pre-period, which indicated that the

PSM was successful in generating comparable groups. However, there were some statistically significant changes from the pre-period to the post-period for both study groups.

Change in pre-period and post-period for select medical comorbidities. Figure 1 highlights the percent change from the pre-period to the post-period for AP group and the AP+P group for comorbidities that were statistically significant. Analyses indicated that for the AP group the incidence of cerebrovascular disease increased from 2002 to 2003 (7.6%, $p < .01$). Additionally, renal disease increased by more than 3 percent of patients for the AP group ($p < .01$). Although there was no statistically significant difference between the pre-period and post-period for the rate of hypertensive disease in the AP group, there was a statistically significant increase of 6.1 percent ($p < .01$) in the AP+P group.

We also found that significantly fewer patients meet the diagnostic criteria of diabetes with chronic complications in both the AP and the AP+P groups in 2003 compared with 2002. The AP group had a 7.5% ($p < .01$) reduction in T2DM patients with chronic complications and the AP+P group had an 8.1% reduction ($p < .01$) of patients diagnosed with diabetes with chronic complications.

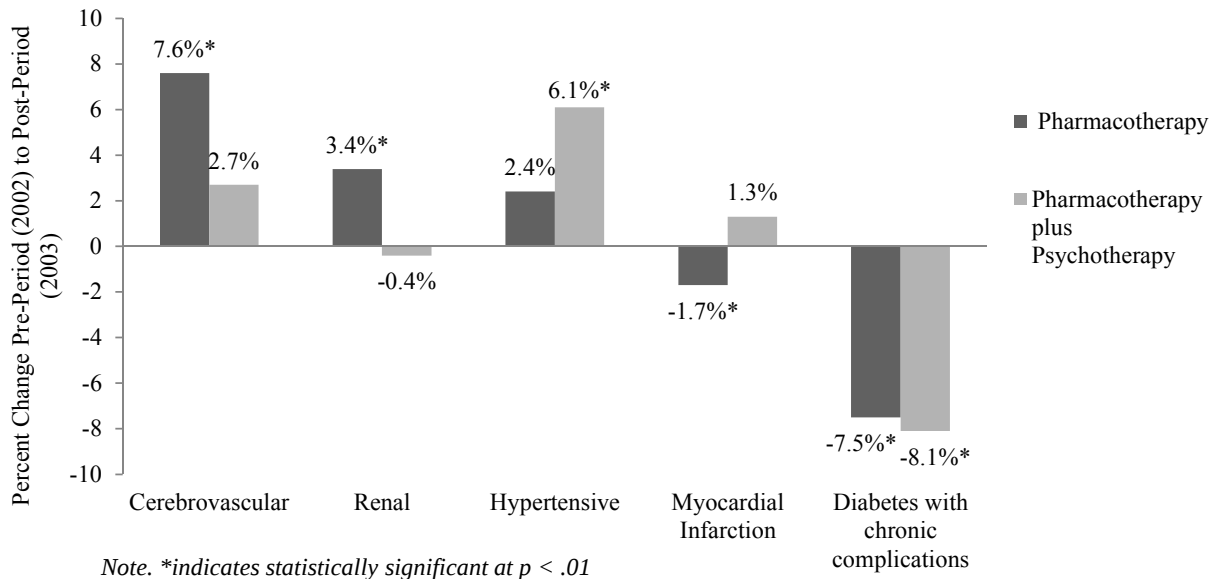

Figure 1. Percent Change in Comorbid Conditions from 2002 to 2003 after PSM, Pharmacotherapy and Pharmacotherapy plus Psychotherapy

Between group differences for total post-period comorbidity. The comorbidity index scores and chronic disease score increased for the AP and the AP+P group. However, there was no statistically significant difference either between the study groups or compared with the pre-period rating. Table 3 highlights the results during the post-period for medical characteristics between the AP and the AP+P group during the post-period.

Post-period T2DM-related comorbidities. The incidence of amputation and renal disease, both complications associated with T2DM, was significantly higher in the AP group than the AP+P group during the post-period. Results of the chi-square analyses indicated that about 1% ($n = 16$) of patients underwent amputation in the 12-month post-period versus 0.6% ($n = 4$) of the patients in the AP+P group ($p = .01$). The incidence of renal disease during the post-period was 6.4% ($n = 59$) for the AP group versus 2.6% ($n = 24$) for the AP+P group ($p < .01$).

We also calculated the OR for comorbid conditions for the AP compared with the AP+P group during the post-period. We found that the odds ratio for amputation in the post-period was 4.0 [99% CI = 1.0, 6.2] for the patients in the AP group compared to patients in the AP+P group. Although a rare event, amputation did appear to be statistically higher in the AP group. Additionally, renal disease had an odds ratio of 1.58 [99% CI = 0.78, 2.2] for patient in the AP group compared with patients in the AP+P group.

Post-period other medical comorbidities. Conversely, some comorbid conditions were higher for the AP+P group than the AP group during the post-period. The incidence of hypertensive disease was 21.1% for the AP group versus 28.2% for the AP+P ($p < .01$) in the 12-month post-period. Myocardial infarction (heart attack) was also higher in the AP+P group with 3.3% ($n = 29$) patients compared to the AP group with 1.4% ($n = 13$) patients. When we analyzed hypertensive disease, it was found that the odds ratio for the AP+P group was 3.6 [99% CI = 2.2, 4.5] compared with the AP group.

Table 3. Medical Variables for Pharmacotherapy and Pharmacotherapy and Psychotherapy after Propensity Score Matching in Post-Period, 2003

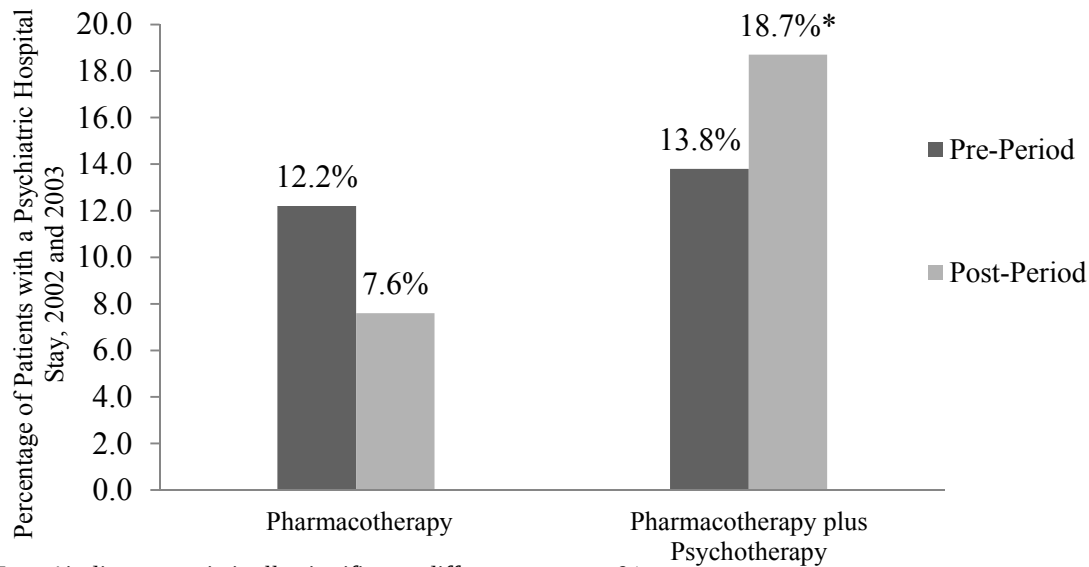

Post-Period Medical Variables	Pharmacotherapy Total (n = 927)		Pharmacotherapy Plus Psychotherapy Total (n = 927)		p-value
	n	%	n	%

Diabetes with chronic complications	221	23.9	220	23.7	0.98
Psychiatric Use-Any Diagnosis					
Hospital Stays*	70	7.6	173	18.7	< 0.01
ED visits	140	15.1	137	14.8	0.85

Note. *indicates statistically significant at $p < .01$

Post-period psychiatric comorbidities. Table 3 shows that overall, the AP+P group had significantly more hospital stays for any psychiatric conditions during the post-period (n = 173 stays, 18.7%) versus patient who in the AP group (n = 70 stays, 7.6%; $p < .01$). ED visits for any psychiatric reason were approximately the same during the post-period for both study groups with approximately 15% of patients with an ED visit during the 12-month post-period.

Change in pre-period and post-period for psychiatric hospitalizations. Figure 2 highlights the pre to post-period change for the AP and AP+P study groups. Psychiatric hospitalizations for any psychological condition changed for both groups in 2003 (Figure 2). For the AP group, psychiatric hospital stays decreased from about 12% to 7.6% ($p < .01$) For the

AP+P group, the percentage of patients with a hospital stay for a psychiatric reason increased during this same period, from 13.8% to 18.7% ($p < .01$).

Note. *indicates statistically significant difference at $p < .01$

Figure 2. Percentage of Patients with a Psychiatric Hospital stay 2002 and 2003, Pharmacotherapy and Pharmacotherapy plus Psychotherapy

Healthcare Utilization

Utilization patterns for the AP and AP+ P group for both the pre and post-period are shown in Table 4. During the pre-period, there were no statistically significant differences between the study groups for total prescription drug use, total healthcare utilization, or T2DM related visits overall. However, during the post-period the AP+P group had more outpatient visits than the AP group ($m = 46.9$, $SD = 42.17$ versus $m = 52.1$, $SD = 49.64$ per patient per year, $p < .01$). The difference in outpatient utilization in part was due to the utilization of behavioral health services related to the study group assignment. During the post-period the AP+P group had an average of 3.46 ($SD = 11.28$) mental health outpatient visits for psychotherapy. The AP group did have more prescriptions filled during the post-period compared to the AP+P group ($m = 20.1$,

$SD = 2.1$ versus $m = 14.6$, $SD = 1.4$, $p < .01$) as well as more prescriptions compared with the pre-period ($m = 13.2$, $SD = 1.0$ versus $m = 20.1$, $SD = 2.3$; $p < .01$). The AP group had more antidepressant medication prescription drug fills than the AP+P group ($m = 6.68$, $SD = 3.24$ versus $m = 4.17$, $SD = 1.78$; $p < .01$).

Contrary to hypotheses, there was not a significantly greater reduction in ED visits following AP+P treatment compared to AP treatment. In fact, there was no statistically significant change in ED visits for either treatment. Finally, for all inpatient hospital stays we found that the average length of stay, in days, significantly increased in the AP+P compared with the AP during the follow-up period ($m = 6.2$, $SD = 3.6$ days versus $m = 3.9$, $SD = 5.2$ days; $p < .01$).

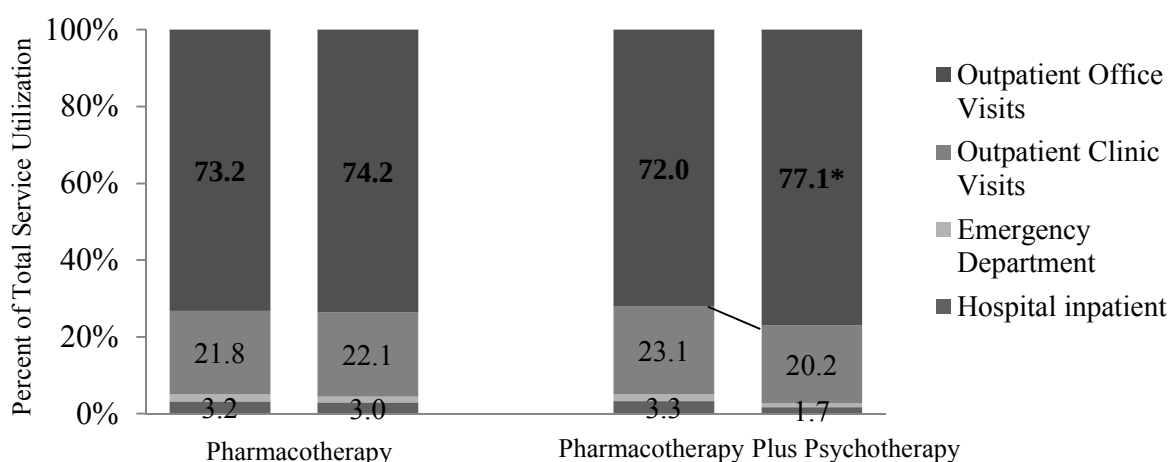

Table 4. All-Cause Utilization and Diabetes-Related Utilization Mean Per Patients in Pharmacotherapy and Pharmacotherapy Plus Psychotherapy Groups Pre-Period Versus Post-Period, 2002 and 2003

	12-month Pre-Period					12-month Post-Period				
	Pharmacotherapy Total (n = 927)		Pharmacotherapy Plus Psychotherapy Total (n = 927)		p-value	Pharmacotherapy Total (n = 927)		Pharmacotherapy Plus Psychotherapy Total (n = 927)		p-value

Note. *indicates a statistically significant difference at $p < .01$

The overall changes in the healthcare utilization are shown in Figure 3. This figure highlights the findings that although service use for all healthcare services is not statistically

significant between groups or during the pre and post-period, there is a statistically significant change to more outpatient utilization for the AP+P group (72.2% to 77.1%, $p < .01$).

Note. *Indicates statistically significant difference, $p < .01$

Figure 3. Percent Change Pre-period to Post-Period for All-cause Utilization, 2002-2003

Adherence. We found that patients in the AP group were less likely to be categorized as having poor adherence to antidepressant medication than the AP+P group. Analyses found that the odds ratio was 1.88, 99% CIs [1.26, 2.69] for poor adherence for the AP+P when compared with the pharmacotherapy group. As the AP group had a higher rate of prescription drug use and higher costs overall, this result is not surprising.

Healthcare Expenditures

Pre-period healthcare expenditures. As total healthcare cost was one of the variables in the PSM, there were no statistically significant difference between the AP and AP+P group during the pre-period. Table 5 indicated that the average total cost for all healthcare services was \$18,600 ($SD = 21,650$) in the AP group per patient per year and \$21,584 ($SD = 35,862$) in the AP+P group per patient per year. The cost per patient for inpatient services, with a mean of

\$4,850 ($SD = \$14,854$) for the AP group and \$6,492 ($SD = \$24,992$) for the AP+P group.

Service costs related to diabetes were \$5,235 ($SD = \$21,209$) for the AP and \$5,768 ($SD = \$25,432$) for the AP+P group during the pre-period. Prescription drugs were about \$4,000 per patient per year for both study groups.

Table 5. Mean Costs for Prescriptions, All Services, and Diabetes-related Services in Pre-Period, Pharmacotherapy and Pharmacotherapy Plus Psychotherapy, 2002

	Pharmacotherapy Total (<i>n</i> = 927)		Pharmacotherapy Plus Psychotherapy Total (<i>n</i> = 927)		p-value
	Mean(\$)	SD	Mean(\$)	SD	
Grand Total, Prescriptions & Services	18,600	21,650	21,584	35,862	0.14

Outpatient Clinic Visits	698	4,180	1,095	5,877	0.25
Outpatient Office Visits	1,053	1,410	910	1,112	0.10

Post-period healthcare expenditures. Table 6 indicates the total cost for the two study groups during the post-period when depression treatment was initiated. The AP group, which included mean costs for antidepressant medication was \$1,101 ($SD = \885) per patient for the 12-month post-period. For the AP+P group the total depression-related treatment cost, which included outpatient psychotherapy and antidepressant medication, was \$905 ($SD = \$3,108$). The difference in the mean costs between the AP and the AP+P group were not statistically significant ($p = 0.04$), but approached significance. Total healthcare service costs were not different between the AP ($m = \$22,313$, $SD = \$45,323$) and the AP+P group ($m = \$23,764$, $SD = \$38,966$). However, there were some differences between the two groups that were expected due

to group assignment. The AP group had significantly more spending for antidepressant drugs during 2003 ($m = \$1,101$, $SD = \$855$) compared with the AP+P group ($m = \$426$, $SD = 690$). As the AP group was shown to have a higher rate of adherence and therefore purchased more drugs during the post-period, this result would be expected. Additionally, the AP+P group would have an added depression-related service, psychotherapy, so the higher costs of outpatient visits for depression is also to be expected. The mean cost, per patient, for a depression-related outpatient service was \$44 ($SD = \659) in the AP group and \$386 ($SD = \$2,736$) for the AP+P group.

However, not just depression-related outpatient costs increased for the AP+P group compared with the AP group. Both T2DM costs and total outpatient costs were higher for the AP+P group during the post-period. The total costs for all outpatient visits and services were significantly higher for the AP+P group ($m = \$8,475$, $SD = \$24,540$) compared with the AP group ($m = \$7,248$, $SD = \$13,041$, $p < .01$). Healthcare costs related to T2DM in an outpatient setting also were higher for the AP+P group, with the mean cost per patient at \$2,781 ($SD = \$15,201$) compared with the AP group mean costs of \$1,896 ($SD = \$8,587$, $p < .01$). This confirms the results that the AP+P group had more overall outpatient healthcare utilization so the additional costs per patient during the 12-month post-period would be expected.

Table 6. Mean Costs for Prescriptions, All Services, and Diabetes-related Services in Post-Period, Pharmacotherapy and Pharmacotherapy Plus Psychotherapy, 2003

Note. *indicates a statistically significant difference at $p < .01$

Difference in 12-month expenditures. Table 7 highlights the mean difference in cost between the 12-month pre-period and the 12-month post-period after the Wilcoxon-signed rank test was complete. A number of services were more expensive, even when depression treatment costs were excluded in the 12-month post-period. For the AP group, cost of all inpatient admission increased by \$328 per patient ($SD = \786, $p < .01$). Inpatient admission related to T2DM were also more expensive during the post-period for the AP group ($m = \$468$, $SD = \$876$, $p < .01$). For the AP group, all outpatient clinic visits were lower during the post-period. Patients saved, on average, \$245($SD = \379, $p < .01$) during the post-period.

For the AP+P group, T2DM inpatient stays were lower during the post-period. T2DM healthcare inpatient stays were, on average, \$675 ($SD = \807, $p < .01$) lower for the AP+P group.

Outpatient services, without the inclusion of depression treatment, were significantly higher for the AP+P group during the post-period. All outpatient services increased \$632 per patient and T2DM outpatient services increased \$688 ($SD = \510, $p < .01$) per patient in the post-period.

Table 7. Mean Cost Difference for 12-month Pre-period and 12-month Post-period for Pharmacotherapy and Pharmacotherapy Plus Psychotherapy, 2002-2003

* Underlined values indicate costs increased from the pre-period to the post-period

Benefit-cost ratio. Table 8 highlights the findings of the BCR. None of the ratios were greater than 1 for the AP or the AP+P group. The results indicated that the total amount of dollars investment for depression treatment was greater than the total cost difference, i.e., cost-savings, for all other healthcare services and for services for T2DM. The total cost for AP depression treatment per patient was over \$1,000 in 2003 (see Table 5) and the total mean difference per

patient excluding depression treatment was approximately \$65 more in 2003. No statistically significant cost savings was found for the AP group.

For the AP+P group a similar result was found. Total healthcare costs, excluding the AP+P treatment, were still about \$345 more in the 2003 than 2002. Outpatient services, excluding those for depression, were the primary driving force for this cost increase with about \$632 ($SD = \789) more per patient in the post-period. For the AP+P group, treatment costs per patient for T2DM were \$162 less than in 2002. Inpatient admissions for T2DM accounted for this difference with a lower cost in 2003 of about \$675 ($SD = \808) per patient. However, the spending on outpatient services was higher in 2003 with an increase of \$688 ($SD = \510) per patient. The total savings for T2DM in 2003 per patient for the AP+P group was offset by the cost for depression treatment at \$905 per patient.

CHAPTER 4

DISCUSSION

Summary of Findings

Following treatment selection of AP or AP+P, patients with depression and T2DM had very few statistically significant differences. Some medical comorbid conditions were different for the two study groups during the 12-months post-period. T2DM-related conditions, including renal disease and amputation were significantly lower for the AP+P group during the post-period compared with the pre-period. The AP also had higher percent of patient diagnosed with renal disease during the post- period than the AP+P group. However, there was an increase in the rate of hypertensive disease for the AP+P group. Psychiatric hospitalizations were also higher in the AP+P group after depression treatment initiation when compared with the pre-period.

For both groups, fewer patients had a diagnosis of diabetes with chronic complications during the post-period compared with the pre-period. Chronic complications including retinopathy, nephropathy, and peripheral neuropathy are an indicator for coronary heart disease (Bailes, 2002). Although the data shows a statistically significant decrease in these diagnoses, there are a number of reasons this could be the case. Fewer patients could have a visit with that specific diagnosis in record for that year and the claims do not reflect the prevalence of complications only the incidence in a given year.

This study indicated that there was a shift in treatment to an outpatient setting for patients with comorbid depression and T2DM once treatment for depression with AP+P was initiated. We found a statistically significant increase in outpatient care for T2DM-related services for the AP+P group, but not for the AP group. Outpatient settings, as distinct from inpatient case, are

more likely to provide routine care, preventative care, and lower cost services to patients. The increase could be due to a number of factors for this group. One reason could be an increase in motivation to seek treatment once a patient has initiated treatment for depression. Studies have indicated that nonpsychiatric outpatient visits are lower for patients with untreated depression than for those who had initiated treatment (Simon, Vonkorff, & Barlow, 1995). Another factor could be physician follow-up and referrals to outpatient care once a patient is engaged in treatment for depression.

With the shift to outpatient care, we did expect to see a parallel change in costs for patients. Although there was no detectable statistically significant difference in overall healthcare costs between the pre and post-periods, there was a statistically significant decrease in costs for patients in the AP+P group for T2DM-related hospital stays. This shift in service use for T2DM care to outpatient settings for the AP+P group may indicate additional cost-savings over time. The 12-month post-period may not be enough time to show the change in a positive clinical status for patients with T2DM. However, the reduction in many of the T2DM-related complications, such as renal disease and amputation, could be attributed to the increase in outpatient care.

Although the AP+P group included an additional service, psychotherapy, there was not an additional cost compared to the AP group. Furthermore, patient selection of AP+P may enhance health-related benefits by increasing T2DM outpatient visits that incorporate preventative care and consequently resulted in the reduction of amputation and renal disease compared to the AP group. Conversely, the AP group had a significantly higher rate of medication adherence compared with the AP+P group. Medication adherence may indicate a

greater motivation to comply with prescription drug regimens and for the AP group resulted in the reduction of hypertensive disease, a medical comorbidity typically treated with medication.

Study Limitations

BCR limitations. The results of the BCR indicated some savings for the AP and the AP+P group. Savings for the AP group included a reduced cost for ED visits and hospitalizations. Savings for the AP+P group included reduced T2DM-related hospitalizations. However, the savings were not statistically significant. Additionally, the overall economic significance could be arguably minimal. The cost differences ranged from \$6 to about \$600 per patient per year and depression treatment accounted for about \$1,000 per year per patient, regardless of treatment group assignment. The results of our analyses, however, cannot model the economic outcomes for untreated depression. Untreated depression would likely result in additional costs, for example, loss of life and work-years due to suicide, absenteeism, loss of potential income, and increased preventable healthcare use. Wang and colleagues (2006) found that the cumulative savings to employers over a 5-year period was about \$2,900 per 1,000 employees. The researchers highlighted that savings for depression are primarily seen in indirect savings from an increase in work productivity. As we only investigated treated depression, for either the AP group or the AP+P group, we cannot account for the possible cost of untreated depression in this population.

Another limitation to the BCR in this study is that we are not able to parse out the specific savings for depression treatment attributed to each service setting. For example, we included the total cost of depression, i.e., AP or AP+P, and then looked at specific savings for ED visits, outpatient settings, and hospitalizations. We were not able to state how much of the savings in each of these service settings was due to the investment in depression treatment. In fact, as the

data are observational, we can only state that costs either increased or decreased. Calculating the precise impact of each depression service on each T2DM service is not possible and outside the scope of claims research.

Claims data limitations. Claims data can be a valuable when used to investigate effective healthcare outcomes, treatment patterns, and health care resource use. However, data used to create MarketScan were originally collected for the purpose of payment not research. Therefore, there are certain limitations associated with using claims data for research. First, the presence of a claim for a filled prescription does not indicate that the medication was consumed or that it was taken as prescribed. Second, medications provided as samples by the physician will not be observed in the claims data. Third, the presence of a diagnosis code on a medical claim is not positive presence of disease, as the diagnosis code may be incorrectly coded or include as probable diagnosis needing further testing, also called the rule-out diagnosis, rather than the actual disease. There is certain information not readily available in claims data that could have an effect on study outcomes, such as certain clinical and disease-specific parameters, including length of time with diabetes.

Additionally, providers often do not write in a diagnosis of depression on the record, despite a prescription for an antidepressant. Studies have indicated that an estimated 45 to 90 percent of depression cases seen in primary care are not coded with a diagnosis of depression (Eisenberg, 1992; Klinkman et al., 1998). It is unclear if failure to properly code is a function of sensitivity to insurance reimbursement, patients' preference to avoid stigma, or primary care doctors' uncertainty. As we are studying depression, this is a very relevant limitation to our study. One alternative way to categorize patients as having depression would have been to investigate all claims with a prescription for an antidepressant. However, providers can also

write prescriptions for off-label use, i.e., for conditions not indicated by the drug. For the purposes of this study, we selected a more conservative analysis and included only those patients with depression coded on their record and who had an antidepressant prescribed.

Finally, the data codes do not specify the type of provider who conducts the psychotherapy, whether by a PhD, Master's level psychologist, or licensed clinical social worker. The data also does not tease out the orientation of the therapy such as CBT, psychodynamic, or others. The database only specified if the therapy is group or individual. Despite these limitations, large claims datasets provide real-world treatment patterns over time for a large number of patients.

Patient selection limitations. The purpose of this study was to investigate the changes in healthcare utilization and costs for patients who had not received depression treatment for at least 12 months in the pre-period. The criterion was therefore limited to patients who did not receive any mental health services for depression in 2002. As this population was enrolled, continuously, in a health insurance plan, it is unclear if patients could have benefited from mental health care prior to 2003. A control group of patients receiving treatment in 2002 would have been helpful in order to assess for comparisons between treated and untreated depression. However, inclusion of a pre-period treatment group would have also raised some concern about confounding variables. For example, we would have been unable to assess how long the patients received treatment prior to 2002. The limitation to the approach in this study was that we selected a less inclusive category of patient which might have limited the generalizability of the study to the population.

By including only patients just initiating depression treatment in the two study groups, we are able to more clearly see the direct average treatment effects of the selected depression treatment on healthcare costs. We were able to more confidently attribute changes in the

healthcare utilization to the effects of the depression treatment rather than an unknown third variable which could have been present if we included patients already receiving mental health care. Additionally, we were able to describe the impact of depression treatment on other service use by using a pre-period and post-period comparison. Previous research has indicated that the year prior to receiving depression treatment and the months following treatment often include a large variability in costs attributed to the typical course of depression (Cui et al., 2013; Maljanen et al., 2012). Researchers found that either pharmacotherapy or psychotherapy treatment is typically correlated with a large increase in all healthcare utilization and costs, not just depression treatment.

Future Directions

Our study did find some evidence that engaging in AP+P treatment for depression is associated with a change in healthcare utilization patterns for T2DM. It was not within the scope of this study, and outside the ability of the database, to explore the specific reasons for this change. It should also be noted that retrospective research is valuable in generating evidence to explore more specific hypothesis that can be tested in a much more controlled research setting. The correlation of initiation in AP+P and the associated increase in outpatient healthcare utilization for comorbid T2DM needs further exploration with RCTs. To date there are no specific studies that have investigated the mechanism for this possible shift in healthcare services.

Additionally, it would be valuable for stakeholders including, insurance companies, providers, and patients to understand the long-term impact of outpatient treatment. More data years could highlight if this pattern of treatment continues or if there is an even larger shift to outpatient settings over. An increase in outpatient services could have an associated decrease in

more expensive inpatient hospitalization and ED visits over time. Future research could provide evidence that cumulative costs-savings may become significant with the additional years of data.

Future research using a more recent dataset may also have drastically different results. This study included claims data prior to the introduction of the Mental Health Parity and Addiction Equity Act of 2008 (MHPAEA). The MHPAEA has allowed increased access to mental health care by preventing private health insurance issuers from imposing less favorable benefit limitations for mental health care compared to medical coverage. Although recent studies have indicated that overall the total healthcare spending has not significantly increased (Mark et al., 2012), no study has looked at the specific impact of the act on depression treatment selection.

Overall, this study was able to provide a broad view of the year following initiation into depression treatment with a focus on the associated differences in T2DM care across the two years. Although descriptive in nature, our results may indicate that treatment for depression influences not just depression, but comorbid chronic conditions such as T2DM. The present study highlights the continued need for researcher to investigate the integration of healthcare services in order to reduce costs, improve health and potentially augment quality of life.

APPENDIX B

CURRENT PROCEDURAL TERMINOLOGY (CPT) CODES FOR OUTPATIENT

PSYCHOTHERAPY

CPT	Description
90804	Individual medical psychotherapy, 20 – 30 minutes
90806	Individual medical psychotherapy, 45 – 50 minutes
90800	Individual medical psychotherapy, 75 – 80 minutes
90853	Group psychotherapy

APPENDIX C

PROPENSITY SCORE MATCHING: CALIPER TOLERANCE RANGE

In the propensity score matching using the caliper method, typically, the optimal value of the tolerance range is not known *a-priori*. For this study we used 0.025 the standard error of the score as has been done in previous claims data research (Huber, Lechner & Wunch, 2010) and justified in Austin (2011). However, for some of the explanatory variables with large variance, for example inpatient psychiatric hospitalizations, there is evidence that a stricter range will give a better estimate and eliminate bias (Zhao, 2004). Therefore, we used a stricter range, 0.01 the standard error, to investigate the difference on the outcome variables. In the re-match we only found that two pairs ($n = 4$) were dropped or re-matched. This had no statistically significant impact on our post-period outcome variables.

In a study by Austin (2009) examining different caliper range methods for one-to-one matching, all examined estimators resulted in a similar number of matched pairs and similar balance of variables between treatment groups. Moreover, PSM with caliper size not exceeding 0.03 tends to result in estimates with minimal relative bias. Based on our additional estimate in the PSM, we found negligible relative bias using stricter criteria in the tolerance range, and therefore did not re-match the sample.

APPENDIX D

CHARLSON COMORBIDITY INDEX SCORE

Comorbidities	ICD-9-CM	Score
Myocardial infarction	410.x, 412.x	1
Congestive heart failure	428.x	1
Peripheral vascular disease	443.9, 441.x, 785.4, V43.4 Procedure 38.48	1
Cerebrovascular disease	430.x--438.x	1
Dementia	290.x	1
Chronic pulmonary disease	490.x--505.x, 506.4	1
Rheumatic disease	710.0, 710.1, 710.4, 714.0-- 714.2, 714.81, 725.x	1
Peptic ulcer disease	531.x--534.x	1
Mild liver disease	571.2, 571.4--571.6	1
Diabetes with chronic complication	250.0--250.6	2
Hemiplegia or paraplegia	344.1, 342.x	2
Renal disease	582.x, 583--583.7, 585.x, 586.x, 588.x	2
Any malignancy, including lymphoma and leukemia, except malignant neoplasm of skin	140.x--172.x, 174.x--195.8, 200.x--208.x	2
Moderate or severe liver disease	456.0--456.21, 572.2--572.8	3
Metastatic solid tumor	196.x--199.1	6
Acquired immunodeficiency syndrome	042.3x	6

Note: for each decade >40 years of age an additional score of 1 is added.

APPENDIX E

INPATIENT PSYCHIATRIC CODES

CPT-Description

99222 Hospital Inpatient Initial Care
99221 Hospital Inpatient Initial Care
99232 Subsequent Hospital Care - Expanded 25
minutes
99231 Subsequent Hospital Care - Simple 15 minutes
99253 Initial Inpatient Consultation 55 minutes
99252 Initial Inpatient Consultation 40 minutes
99251 Initial Inpatient Consultation

ICD-9-CM for mental health conditions (ED and Inpatient ONLY)

290-299 Mental Disorders
V11-79 Self-harm and Suicide

APPENDIX F

RESULTS OF BOOTSTRAP ANALYSIS

To examine the impact of depression treatment selection we used a technique called nonparametric bootstrapping (An & Ahmed, 2008; Janssen & Pauls, 2003; Mackinnon, 2002).. Nonparametric bootstrapping is a technique which creates a distribution of the mean cost differences between groups through re-sampling, with replacement, from the observed cost data. Bootstrapping takes, at random, values from the study sample and calculates the probability of drawing that value. This relative frequency of the value, in our study the mean difference in costs, is considered to be the estimate of the sampling distribution. Bootstrapping is an alternative for analysis of skewed cost data because it uses a nonparametric approach, which can directly address arithmetic means without making assumptions about the shape of the distribution. As previously mentioned, healthcare data is heavily skewed right making parametric testing less effective. In our study, Bootstrap re-sampling ($n = 1,000$ iterations) was used to provide a nonparametric comparison of total mean costs and T2DM-related costs across all settings. The estimated mean, using bootstrapping, was then used in the ratios constructed for the costs-benefit analyses and to produce 99% confidence intervals around the mean. After generating the new sample we compared the BCR to a null hypothesis, or an expected value, of 1.

*Mean Cost Difference for 12-month Pre-period and 12-month Post-period for
Pharmacotherapy and Pharmacotherapy Plus Psychotherapy after Bootstrap Analysis*

	Pharmacotherapy		Pharmacotherapy Plus Psychotherapy	
	Total		Total	
	(n = 927)		(n = 927)	
	Per Patient Cost		Per Patient Cost	
	(\$) Difference (pre-	99% CI	(\$) Difference (pre-	99% CI
	post)		post)	
All Healthcare Services (minus depression-related)				
Emergency Department Visits	45.78	32.15, 56.78	3.58	2.05, 6.89
Inpatient Admissions	<u>389.78</u>	<u>150.67, 745.23</u>	180.38	150.23, 205.67
All Outpatient Visits and Services	155.23	256.02, 330.24	<u>425.14</u>	<u>302.01, 502.01</u>
Outpatient Clinic Visits	278.92	245.91, 369.04	<u>521.40</u>	<u>579.25, 631.9</u>
Outpatient Office Visits	98.23	72.54, 106.82	<u>178.25</u>	<u>95.34, 290.67</u>
Diabetes-related Services				
Emergency Department Visits	37.78	21.06, 45.98	5.58	2.98, 11.87
Inpatient Admissions	<u>390.99</u>	<u>207.54, 435.04</u>	615.02	480.20, 705.85
All Outpatient Visits and Services	<u>138.42</u>	<u>67.23, 239.32</u>	<u>428.98</u>	<u>387.24, 598.70</u>
Outpatient Clinic Visits	<u>205.05</u>	<u>180.92, 236.67</u>	<u>458.74</u>	<u>287.21, 399.01</u>
Outpatient Office Visits	228.87	165.12, 278.23	189.42	112.34, 270.26

* Underlined values indicate costs increased from the pre-period to the post-period
